Assignment 2 Due 10/7 at Midnight

Julia Schedler

NOTE: I forgot to include a relevant detail for Part 2, number 7. The change is **bolded.** Sorry!!! Part 2 number 8 should be easier to answer now.

Part 1: Math

In class, we have worked with "Signal plus noise Model" (equation 1.5)

$$\mbox{Model: } x_t=2\cos(2\pi\frac{t+15}{50})+w_t$$
 Mean function: $\mathbb{E}(x_t)=2\cos(2\pi\frac{t+15}{50})$

- 1. [5 points] The mean function is derived in Example 2.4. Describe what happens in each step of the computation [3 points], and provide a "math stress" rating (1 = effortless, 100 = nightmare) and 3 emojis[2 points]. This is personal and there is no right answer.
- 2. [5 points] Is the signal plus noise model stationary in the mean?
- 3. [5 points] Write down $\gamma_x(s,t)$, the autocovariance function of x_t [3 points]. You may accomplish this in any way, including asking me personally in office hours or asking a classmate. Just make sure you cite the source![2 points]
- 4. [6 points] Consider the model:

$$y_t = x_t - 2\cos(2\pi\frac{t+15}{50})$$

Compute the mean function of y_t [3 points]. Is y_t stationary in the mean?[1 point] How do you know?[2 points]

Part 2: Code

Note: I have set the code chunks here to have eval: false in the code chunk. Change that to true so that I can run your code easily.

- 0. [5 points] All your code runs without errors (unless that's the point), and if there is a message, explain what it means. (Bonus: to be nice to me, submit a rendered pdf)
- 1. [5 points] Simulate from an AR(1) process with coefficient 0.7 and 10 data points.

```
library(astsa)
# your code here
```

[6 points] Look at the documentation for the stats::lag function (run ?lag in the console). State what package the function is in and what the function does[4 points].
 Using k = 1 compute a lag(1) version of x_t that you simulated above[2 points].

```
x_t_lag1 <- # your code here</pre>
```

3. [3 points] Run the following code and compare x_t and x_t_lag1.

```
cbind(x_t, x_t_lag1)
```

4. Make a time series plot of x_t and x_t_1. Do you notice the same features as when in the previous question?

```
# your code here
```

5. Run the below code. Why are the plots different? Are either particularly useful?

```
plot(x_t, x_t_lag1)
plot(as.vector(x_t), as.vector(x_t_lag1))
```

6. Instead of using stats::lag, use dplyr::lag to create a new version of x_t_lag. Repeat the code from steps 2-5. Describe how the output has changed.

```
x_t_lag1 <- dplyr::lag(# your code here)</pre>
```

7. Re-simulate an AR(1) process as in number 1, but this time with 100 observations. Also recompute x_t_lag1. Fit an intercept-free regression model to predict x_t from x_t_lag. Provide the value of the slope estimate and interpret the value in the context of this simulation.

linear_model <- # your code here</pre>

8. [11 points] Plot the acf of x_t[2 points] and the acf of the residuals from the regression model[4 points]. Which looks more like white noise?[2 points] What does this tell you about the temporal structure in x_t and its residuals?[3 points]

your code here

Part 3: Reading

[9 points] Read sections 2.8 and 2.9 from Forecasting Principles and Practice. Make 3 connections [3 points each] to content from the course textbook (equations or similar examples.).
